STOCHASTIC INTEGRALS OF WEIGHTED EMPIRICAL PROCESSES AND AN APPLICATION TO THE LIMIT DISTRIBUTION OF LINEAR RANK STATISTICS UNDER ALTERNATIVES

Abbreviated Title: STOCHASTIC INTEGRALS OF WEIGHTED EMPIRICAL PROCESSES

By Navaratna S. Rajaram Kent State University

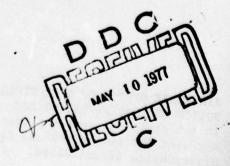

(series a from me to mm)

Introduction: The distribution under alternatives of a simple linear rank statistic S_n (defined in (2.1)) is governed by the following entities: a set of regression constants (C_{n1}, \dots, C_{nn}) , scores (a_{n1}, \dots, a_{nn}) and distribution functions (F_{n1}, \dots, F_{nn}) . One usually assumes the scores to be generated by a known function φ .

AMS 1970 subject classification: Primary 60H05: secondary 60B10, 62G10.

Key words and phrases: Linear rank statistics; weighted empirical processes; stochastic integrals; reproducing kernel Hilbert spaces.

For the important special case arising when one takes for some $m < n, C_{n1} = \cdots = C_{nm} = \frac{1}{m} \text{ and } C_{nm+1}, \cdots, C_{nn} = 0; F_{n1} = \cdots = F_{nm} = F$ and $F_{nm+1} = \cdots = F_{nn} = G$, Chernoff-Savage (1958) obtained the asymptotic normality of S, with some restrictions on the growth rates of the first two derivatives of φ . The same results have since been proved by Govindarajulu-Le Cam-Raghavachari (1966) and Puri-Sen (1971) with milder conditions on w. A far-reaching generalization of these results is due to Hajek (1968). In a remarkable paper, Pyke-Shorack (1968) provided an ACCESSION IO alternative approach to the Chernoff-Savage theorems by considering the weak convergence of a two sample empirical process to a Gaussian process. UNAMADUNCEB MISTIFICATION This approach has had a very significant impact on research practices in the area of nonparametric statistics and there now exists a substantial JIAYA\ ROITUSIRTE body of literature devoted to stochastic processes arising in such problems. In spite of this, however, techniques of neither the Pyke-Shorack kind nor of the Chernoff-Savage kind have been applied to problems of the regression type. The method of attack for such problem has for the most part been along the lines of Hajek (1968), Puri-Sen (1969), Hoeffding (1973), to name a few. We have been able to obtain results of the type given in Hájek (1968) both by the Chernoff-Savage approach and by a method involving convergence of certain stochastic processes. The latter is given in this paper; the former, together with some results on convergence rates is published separately. (See Puri-Rajaram (1977).)

As is well known, the classical weak convergence method, to be found, for example, in Billingsley (1968) or Pyke-Shorack (1968) generally entail securing certain bounds on the sample path fluctuations of the processes involved, usually with the help of certain refined metrics. If the distributions are allowed to vary a great deal, any analysis of the sample paths can become extremely involved. Further, unlike statistics of the

Kolmogorov-Smirnov type which are measures of the maximum sample path fluctuation, statistics of the regression type are weighted sums involving ranks and any sample path behavior as such is not directly relevant. Taking these factors into consideration, we have adopted an approach which uses only the second order properties of the processes involved, thus circumventing the need for sample path analysis.

It is well known that a second order process, that is to say a stochastic process X(t) whose variance K(t, t) is finite for all values of t, spans a reproducing kernel Hilbert space with kernel K(s, t) = Cov(X(s), X(t)). We exploit the fact that linear rank statistics can be approximated by elements of the Hilbert space spanned by suitably defined empirical processes. In general, such a Hilbert space does not characterize the process spanning it completely. However, the spanning process if Gaussian, is completely determined by its Hilbert space. We establish the asymptotic normality of linear rank statistics by proving their convergence to a point in the Hilbert space spanned by a Gaussian process. Integrals of the type considered here are used in a wide range of applications; Parzen (1958), for example, has used them in his basic work in time series analysis. But the application given here for a problem in nonparametric statistics appears to be new. Brown (1970) has some interesting results on convergence in distribution of stochastic integrals. The basic reference on reproducing kernel Hilbert spaces is Aronszajn (1950). Yosida (1972) also has useful results on reproducing kernels.

Our conditions on the score generating functions are the same as those in Puri-Sen (1971), being somewhat stronger than those of Hājek (1968) but less stringent than in Chernoff-Savage (1958). However, the centering constant, μ_n , is used throughout in the place of E(S_n) used by Hājek. This,

in addition to being easier to compute, serves to unify the results of Hájek (1968) and Hoeffding (1973). We also examine the asymptotic degeneracy of S_n and in this respect our results extend both the Hájek and the Chernoff-Savage, Puri-Sen results.

2. Definitions and Terminology.

Let X_{n1} , X_{n2} , ..., X_{nn} be a sequence of independent random variables with <u>continuous</u> distribution functions F_{n1} , F_{n2} , ..., F_{nn} respectively. Let R_{ni} be the rank of X_{ni} among (X_{n1}, \dots, X_{nn}) , that is

$$R_{ni}$$
 = (number of $X_{nj} \le X_{ni}$); j = 1, ..., n.

We define a simple linear rank statistic by

(2.1)
$$S_n = \sum_{i=1}^n C_{ni} a_n(R_{ni})$$

where, (C_{nl}, \dots, C_{nn}) , $(a_n(1), \dots, a_n(n))$ are known constants, C_{ni} being known as regression constants and $a_n(i)$ as scores. One usually assumes $a_n(i)$ to be generated by a known real-valued function ϕ defined on (0, 1) in either of the following ways:

(2.2) (a)
$$a_n(i) = \varphi(\frac{i}{n+1});$$
 (b) $a_n(i) = E \varphi(U_n^{(i)})$

where $U_n^{(i)}$ is the ith order statistic among n independent random variables distributed uniformly over (0, 1). We shall assume (2.2) (a), namely, $\mathbf{a}_n(\mathbf{i}) = \phi(\frac{\mathbf{i}}{n+1})$. Extension to case (b) can be done in one of the several ways but has little to do with the techniques developed in this paper and need not concern us. Thus, by (2.2) (a), we can write S_n as

(2.3)
$$S_{n} = \sum_{i=1}^{n} C_{ni} \varphi(\frac{R_{ni}}{n+1}).$$

For a fixed x, we define the empirical distribution function $H_n(x)$ for the sample X_{n1} , ..., X_{nn} , by

(2.4)
$$H_{n}(x) = \frac{1}{n} \sum_{i=1}^{n} I(X_{ni} \le x)$$

where the "indicator function" I() is defined by

(2.5)
$$I(X_{ni} \le x) = l \text{ if } X_{ni} \le x$$
$$= 0 \text{ if } X_{ni} > x.$$

We also define the combined sample distribution function by

(2.6)
$$F_n(x) = H(x) = \frac{1}{n} \sum_{i=1}^{n} F_{ni}(x) .$$

For the special case, m < n

$$C_{nl} = \cdots = C_{nm} = \frac{1}{m}, C_{nm+1} = \cdots = C_{nn} = 0$$
 $F_{nl} = \cdots = F_{nm} = F, F_{nm+1} = \cdots = F_{nn}.$

Pyke-Shorack (1968) consider the two-sample empirical process defined by

(2.7)
$$L_n(t) = \sqrt{n} \{F_m(H_n^{-1}(t)) - F(H^{-1}(t))\}$$

where $F_m(x)$ is the empirical distribution function corresponding to the sample (X_{nl}, \dots, X_{nm}) . They obtain the asymptotic normality of S_n presponding to the two sample cases (the Chernoff-Savage theorem) by proving the weak convergence of $L_n(t)$ to a Gaussian process and also its convergence in some refined metrics. Thus for the general regression case, that is, when S_n is defined by (2.1) or (2.3), it is natural to consider the process defined by

(2.8)
$$L_{n,c}(t) = \sum_{i=1}^{n} C_{ni} \{I(X_{ni} \leq H_{n}^{-1}(t)) - F_{ni}(H^{-1}(t))\}.$$

Unfortunately this process is much too complex and classical weak convergence methods entail a detailed study of the sample path fluctuations of the process. Hence, we will avoid this by basing our approach on the second order behavior.

3. Stochastic Integrals of Second Order Stochastic Processes.

Let $\{X(t): t \in T\}$ be a real-valued second order stochastic process with the kernel K(s, t) = E[X(s)|X(t)]. Let $\{Y(t): t \in T\}$ be another real-valued second order stochastic process with the kernel R(s, t) = E[Y(s)|Y(t)]. We always assume that T is an interval on the real line.

Let T = [a, b] where $a \le b$ are real numbers. We define the second order stochastic integral of X(t) with respect to Y(t) as follows. We follow essentially Loeve (1963).

Let
$$D_T$$
: $a = t_1 < t_2 < \cdots < t_{n+1} = b$.

Define the random step function

(3.1)
$$\int_{T} X_{D_{T}}^{(t)} d Y(t) = \sum_{k=1}^{n} X_{k} \{Y(t_{k+1}) - Y(t_{k})\}$$

where

$$X_k = X(t_k'), t_k \leq t_k \leq t_{k+1}.$$

Then the stochastic integral (second order) of X(t) with respect to Y(t) is defined by

$$\int_{\mathbb{T}} X(t) dY(t) = \lim_{\substack{\text{max} \\ 1 \leq k \leq n}} |t_{k+1} - t_k| \to 0 \int_{\mathbb{T}} X_{D_{\mathbb{T}}}(t) dY(t)$$

if it exists, where l.i.m. means limit in the quadratic mean.

Often we will need to define it as an improper integral on T = (a,b). Then we take T' = $[\alpha,\beta]$, a < α < β < b and first define as before

$$\int_{\mathbf{T}^{1}} X(t) d Y(t)$$

and then define the improper integral

(3.4)
$$\int_{T} X(t) d Y(t) = 1.i.m. \int_{T'} X(t) d Y(t)$$

$$\alpha \rightarrow a$$

$$\beta \rightarrow b$$

if it exists.

Remark 1. These integrals depend on the "increments" of Y(t) and not directly on Y(t) itself.

The following theorem ensures the existence of such an integral.

Theorem 3.1. Let the second order stochastic process X(t) with the kernel K(s, t) be independent of the "increments" of the second order process Y(t) with the kernel R(s, t). Then the stochastic integral $\int_T X(t) d Y(t) d Y($

exists as a Riemann-Stieltjes (perhaps improper) integral.

Proof. See Loéve (1963).

Remark 2. Very often in applications, Y(t) will be a nonrandom function g(t). Then theorem 3.1 reduces to the following

Corollary 3.2. The stochastic integral $\int_T X(t) d g(t)$ exists if and only if $\int_T \int_T K(s, t) d g(s) d g(t)$ exists as a Riemann-Stieltjes (perhaps improper) integral.

Proof. Immediate from theorem 3.1.

The following property of Gaussian processes proves very useful.

Theorem 3.3: If Y(t) is a nonrandom function integration of a Gaussian process with respect to Y(t) preserves normality.

Proof. See Loeve (1963).

4. Second Order Properties of Weighted Empirical Processes.

Let X_{n1} , X_{n2} , ..., X_{nn} , ... be independent random variables with the corresponding distribution functions F_{n1} , F_{n2} , ..., F_{nn} , ... which are continuous. We define

(4.1)
$$F_n = \frac{1}{n} \sum_{i=1}^{n} F_{ni}$$
.

Let C_{nl}, ..., C_{nn} be known constants. We shall investigate the second order properties of the two processes,

$$(4.2) X_n(t) = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \{I(X_{ni} \le F_n^{-1}(t)) - F_{ni}(F_n^{-1}(t))\}$$
$$= \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \{I(X_{ni} \le F_n^{-1}(t) - t\}.$$

(4.3)
$$Y_{n}(t) = \frac{1}{s} \sum_{i=1}^{n} C_{ni} \{I(X_{ni} \leq F_{n}^{-1}(t)) - F_{ni}(F_{n}^{-1}(t))\}, \quad 0 < t < 1,$$

where $s_n > 0$ is a normalizing constant and I() is defined by,

(4.4)
$$I(X_{ni} \le y) = \begin{cases} 1 & \text{if } y \ge X_{ni} \\ 0 & \text{otherwise.} \end{cases}$$

The process $X_n(t)$ is, of course, the well known empirical process and has been extensively studied. We shall closely study the process $Y_n(t)$. The process $Y_n(t)$ as well as the process $L_{n,c}(t)$ defined in (2.8) have been considered by Koul (1970) and Koul and Standte (1972) respectively. Our approach, however, is significantly different.

Lemma 4.1:
$$E X_n(t) = E Y_n(t) = 0$$

(4.5)
$$E[X_n(s) X_n(t)] = K_n(s, t)$$

= $s \wedge t - \frac{1}{n} \sum_{i=1}^{n} F_{ni}(F_n^{-1}(s)) \cdot F_{ni}(F_n^{-1}(t))$

(4.6)
$$E(Y_n(s) Y_n(t)] = R_n(s, t)$$

$$= \frac{1}{s} \sum_{i=1}^{n} C_{ni}^2 \{F_{ni}(F_n^{-1}(s)) \wedge F_{ni}(F_n^{-1}(t)) - F_{ni}(F_n^{-1}(s)) F_{ni}(F_n^{-1}(t))\}$$

where for any two real numbers a and b, a A b = min (a, b).

<u>Proof.</u> Proof of E $X_n(t) = E Y_n(t) = 0$ is obvious. Further (4.5) is a special case of (4.6) and hence it suffices to prove the latter alone.

Without loss of generality let $s \le t$. Let $u = F_n^{-1}(s) \le v = F_n^{-1}(t)$. Then we have

$$\begin{split} &Y_{n}(s)Y_{n}(t) = \frac{1}{s_{n}^{2}} \sum_{i,j=1}^{n} C_{ni}C_{nj} \{I(X_{ni} \leq u) - F_{ni}(u)\} \{I(X_{nj} \leq v) - F_{nj}(v)\} \} \\ &= \frac{1}{s_{n}^{2}} \sum_{i=1}^{n} C_{ni}^{2} \{I(X_{ni} \leq u) - F_{ni}(u)\} \{I(X_{ni} \leq v) - F_{ni}(v)\} \\ &+ \frac{1}{s_{n}^{2}} \sum_{i \neq j} C_{ni}C_{nj} \{I(X_{ni} \leq u) - F_{ni}(u)\} \{I(X_{nj} \leq v) - F_{nj}(v)\}. \end{split}$$

On taking expectations, the expectation of the second sum vanishes and is the first sum

$$\begin{split} \mathbb{E}[\{\mathbb{I}(X_{\text{ni}} \leq u) - \mathbb{F}_{\text{ni}}(u)\}\{\mathbb{I}(X_{\text{ni}} \leq v) - \mathbb{F}_{\text{ni}}(v)\}] \\ &= \mathbb{F}_{\text{ni}}(u) \wedge \mathbb{F}_{\text{ni}}(v) - \mathbb{F}_{\text{ni}}(u) \times \mathbb{F}_{\text{ni}}(v). \end{split}$$

This establishes (4.6).

Next we examine the Ly-convergence of the processes Yn(t).

<u>Definition</u>. A sequence $Y_n(t)$ of second order processes converges in L_2 to another (second order) process Y(t) if and only if

$$\|Y_n(t) - Y(t)\| = \{Var(Y_n(t) - Y(t))\}^{1/2} \longrightarrow 0$$

as $n \rightarrow + \infty$, for each t.

We then write

$$Y_n(t) \xrightarrow{I_2} Y(t)$$

or

$$\|Y_n(t) - Y(t)\| \longrightarrow 0.$$

We next obtain criteria for L_2 convergence of the processes $Y_n(t)$ defined in (4.3).

Theorem 4.2. The second order processes Yn(t) with Rn(t) as their kernel (defined by (4.3) and (4.6) respectively) converge to a second order process Y(t) if and only if, for each t,

Further, if (4.7) holds, the kernel of Y(t) is given by

(4.8)
$$E[Y(s) Y(t)] = R(s, t) = \lim_{n \to +\infty} R_n(s, t).$$

In statistical applications, we have a continuous sampling situation; that is to say if $m \le n$, we have, $X_{nl} = X_{ml}$, ..., $X_{nm} = X_{mm}$. Then the above theorem becomes a more precise

Corollary 4.3. Let $n \ge m$ and the sequences be such that, $X_{nj} = X_{nj}, \ j \le m. \quad \underline{\text{Then the process }} Y_n(t) \ \underline{\text{defined as before converges to a}}$ $\underline{\text{process }} Y(t) \ \underline{\text{with kernel }} R(s, t) = \lim_{n \to \infty} R_n(s, t) \ \underline{\text{if and only if }}$

(4.9)
$$\lim_{\substack{m \to +\infty \\ n \to +\infty}} \frac{1}{s_n^s} \sum_{i=1}^m C_{ni} C_{mi} \left\{ F_{ni} \left(F_m^{-1}(t) \right) \wedge F_{ni} \left(F_n^{-1}(t) \right) - F_{ni} \left(F_n^{-1}(t) \right) F_{ni} \left(F_n^{-1}(t) \right) \right\}$$

exists and is finite for each t.

Theorem 4.2 is proved by a direct application of theorem A, page 469 of Loéve (1963). Therefore, we shall only prove corollary 4.3.

Proof of Corollary 4.3. Note that by the hypothesis, $F_{nl} = F_{ml}, \cdots, F_{nm} = F_{mm}, m \le n. \quad \text{But } F_n = \frac{1}{n} \sum_{i=1}^{n} F_{ni} \text{ and } F_m = \frac{1}{m} \sum_{i=1}^{m} F_{ni} \text{ could be different.} \quad \text{Also, } C_{ni} \text{ may not equal } C_{mi} \text{ and, } s_n \text{ and } s_m \text{ could also be different.}$

In order to simplify the notation, we shall write $u=F_n^{-1}(t)$ and $v=F_m^{-1}(t)$. Then

$$\begin{aligned} & (4.10) \quad Y_{n}(t) \; Y_{m}(t) \\ & = \frac{1}{s_{n}s_{m}} \; \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq m}} C_{ni}C_{mj} \; \{I(X_{ni} \leq u) - F_{ni}(u)\}\{I(X_{mj} \leq v) - F_{nj}(v)\} \\ & = \frac{1}{s_{n}s_{m}} \; \sum_{i=1}^{m} \; C_{ni}C_{mi} \; \{I(X_{ni} \leq u) - F_{ni}(u)\}\{I(X_{mi} \leq v) - F_{mi}(v)\} \\ & + \frac{1}{s_{n}s_{m}} \; \sum_{i \neq j} \; C_{ni}C_{mj} \; \{I(X_{ni} \leq u) - F_{ni}(u)\}\{I(X_{mj} \leq v) - F_{mj}(v)\} \end{aligned}$$

where we have used the fact that $X_{ni} = X_{ni}$ and $F_{ni} = F_{mi}$ for $i \leq m$.
Observe that:

(i) When i \neq j, I(X $_{\text{mi}}$ \leq \cdot) and I(X $_{\text{mj}}$ \leq \cdot) are independent. Hence

$$E\{[I(X_{ni} \le u) - F_{ni}(u)] [I(X_{nj} \le v) - F_{mj}(v)]\} = 0.$$

(ii) When i = j,

$$\begin{aligned} & \text{[I(X}_{\text{ni}} \leq \text{u}) - \text{F}_{\text{ni}}(\text{u})] \text{ [I(X}_{\text{ni}} \leq \text{v}) - \text{F}_{\text{ni}}(\text{v})]} \\ & = \text{I(X}_{\text{ni}} \leq \text{u}) \text{ I(X}_{\text{ni}} \leq \text{v}) - \text{F}_{\text{ni}}(\text{v}) \text{ I(X}_{\text{ni}} \leq \text{u})} \\ & = \text{F}_{\text{ni}}(\text{u}) \text{ I(X}_{\text{ni}} \leq \text{v}) + \text{F}_{\text{ni}}(\text{u}) \text{ F}_{\text{ni}}(\text{v}). \end{aligned}$$

In (4.11) for the first term,

 $E\{I(X_{ni} \leq u) \ I(X_{ni} \leq v)\} = F_{ni}(u \wedge v) = F_{ni}(u) \wedge F_{ni}(v).$ Taking expectations in (4.11), we get

$$(4.12) E\{[I(X_{ni} \le u) - F_{ni}(u)][I(X_{ni} \le v) - F_{ni}(v)]\}$$

$$= F_{ni}(u) \wedge F_{ni}(v) - F_{ni}(u) F_{ni}(v)$$

$$= F_{ni}(F_{n}^{-1}(t)) \wedge F_{ni}(F_{m}^{-1}(t)) - F_{ni}(F_{n}^{-1}(t)) F_{ni}(F_{m}^{-1}(t)).$$

Thus by taking expectations of (4.10) and substituting (4.12) and (i) we get the expression in (4.9). An application of theorem 4.2 proves the corollary.

5. Limit Distributions of the Processes $X_n(t)$ and $Y_n(t)$.

Since $X_n(t)$ is a special case of $Y_n(t)$, it suffices to establish the results for the latter. We have the following theorem:

Theorem 5.1. For the processes Yn(t), let

- (i) conditions of theorem 4.2 (or of corollary 4.3) hold; and let
- (ii) $(\max_{1 \leq i \leq n} |C_{ni}|) s_n^{-1} = O(\frac{1}{\sqrt{n}}).$

Then
$$Y_n(t) \xrightarrow{L_2} Y(t) \xrightarrow{where} Y(t) \xrightarrow{is} Gaussian with the kernel$$

$$R(s, t) = \lim_{n \to +\infty} R_n(s, t).$$

<u>Proof.</u> L_2 -convergence and the convergence of the kernels are immediate consequences of condition (i). It suffices to prove the asymptotic normality of the finite dimensional distributions of $Y_n(t)$.

Let t_1, t_2, \dots, t_k be any fixed elements in T. Consider the random vector $(Y_n(t_1), \dots, Y_n(t_k))$.

We use the Cramer-Wold criterion.

Let a_1, \dots, a_k be arbitrary constants. It suffices to show that

(5.1) $\sum_{j=1}^{k} a_j Y(t_j) \text{ is asymptotically normal.}$

To simplify the notation, we write

$$u_j = F_n^{-1}(t_j), j = 1, \dots, k.$$

Then

(5.2)
$$\sum_{j=1}^{k} a_{j} Y(t_{j}) = \sum_{j=1}^{k} a_{j} \left\{ \sum_{i=1}^{n} \frac{C_{ni}}{s_{n}} \left[I(X_{ni} \leq u_{j}) - F_{ni}(u_{j}) \right] \right\}$$

$$= \sum_{i=1}^{n} \frac{C_{ni}}{s_{n}} \left\{ \sum_{j=1}^{k} a_{j} \left[I(X_{ni} \leq u_{j}) - F_{ni}(u_{j}) \right] \right\}.$$

Let $\alpha_{ni} = \frac{\sqrt{n} c_{ni}}{s_{ni}}$. Observe that

(5.3)
$$\alpha_{ni} = 0(1) \text{ in n.}$$

Thus we can write,

(5.4)
$$\sum_{j=1}^{k} a_{j} Y(t_{j}) = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \alpha_{ni} \left\{ \sum_{j=1}^{k} a_{j} [I(X_{ni} \leq u_{j}) - F_{ni}(u_{j})] \right\}.$$

In (5.4), observe that by (5.3), each random variable

$$\alpha_{\text{ni}} \sum_{j=1}^{k} a_{j}[I(X_{\text{ni}} \leq u_{j}) - F_{\text{ni}}(u_{j})]$$

is bounded.

Let

(5.5)
$$\sigma_{ni}^2 = \alpha_{ni}^2 \text{ Var } \{ \sum_{j=1}^k a_j [I(X_{ni} \le u_j) - F_{ni}(u_j)] \}$$

and

(5.6)
$$\sigma_{n}^{2} = \sum_{i=1}^{n} \sigma_{ni}^{2}$$
.

Then by the bounded Liapunov theorem, $\sum_{j=1}^{k} a_j Y(t_j)$ is asymptotically normal provided $\sigma_n^2 \to +\infty$; if not, it is degenerate. In any event, $Y_n(t)$ is asymptotically normal, possibly degenerate. We shall examine degeneracy more closely in section 8.

6. Asymptotic Normality of Certain Stochastic Integrals of the Processes $X_n(t)$ and $Y_n(t)$.

In this section we consider the stochastic integrals X_n and Y_n given by

(6.1)
$$X_n = \frac{1}{\sqrt{n s_n}} \int_0^1 X_n(t) \varphi'(t) dC(t)$$

and

(6.2)
$$Y_n = \int_0^1 Y_n(t) \varphi'(t) dt$$

where

(6.3)
$$C(t) = \sum_{i=1}^{n} C_{ni} F_{ni} (F_{n}^{-1} (t))$$

and ϕ is a known function.

In the next theorem we obtain bounds for the variances of X_n and Y_n . This in turn will enable us to prove the asymptotic normality of S_n defined in (2.1). The variance bound for Y_n is also of independent interest because it gives a condition on ϕ for the process $\phi'(t)$ $Y_n(t)$ to possess kernels of the so-called Hilbert-Schmidt type, uniformly in n.

Theorem 6.1. Let $X_n(t)$, $Y_n(t)$ and their corresponding integrals X_n and Y_n be as defined. Let the following conditions hold:

(a)
$$\max_{1 \le i \le n} \left| \frac{c_{ni}}{s_n} \right| = O(\frac{1}{\sqrt{n}})$$

(b) there exists $\delta > 0$ such that for some K (generic)

$$|\varphi'(t)| \le K\{t(1-t)\}^{\delta-3/2}, 0 < t < 1.$$

Then

(6.4)
$$\text{Var } Y_n \leq O(1) \left[\int_0^1 |\phi'(t)| \left\{ R_n(t, t) \right\}^{1/2} dt \right]^2 \leq \frac{\kappa^2}{\delta^2} 2^{5-4\delta}$$

and

(6.5)
$$\operatorname{Var} X_{n} \leq O(1) \left[\int_{0}^{1} |\varphi'(t)| \left\{ K_{n}(t, t) \right\}^{1/2} dt \right]^{2} \leq \frac{K^{2}}{\delta^{2}} 2^{5-4\delta}.$$

In (6.8) observe that,

$$0 \le F_{ni}(F_n^{-1}(t)) \le 1$$

and

$$0 \le 1 - F_{ni}(F_n^{-1}(t) \le 1.$$

Thus

(6.9)
$$R_n(t, t) \le O(1) \frac{1}{n} \sum_{i=1}^n F_{ni}(F_n^{-1}(t)) = O(1)t$$

and

(6.10)
$$R_n(t, t) \leq O(1) \frac{1}{n} \sum_{i=1}^{n} [1 - F_{ni}(F_n^{-1}(t))] = O(1)(1 - t).$$

Also,

(6.11)
$$\int_0^1 \{R_n(t, t)\}^{1/2} |\varphi'(t)| dt$$

$$= \int_{0}^{1/2} \{R_{n}(t, t)\}^{1/2} |\varphi'(t)| dt + \int_{1/2}^{1} \{R_{n}(t, t)\}^{1/2} |\varphi'(t)| dt.$$

First consider

$$\begin{aligned} & |\int_{0}^{1/2} \{R_{n}(t, t)\}^{1/2} |\phi'(t)| dt | \leq O(1) \int_{0}^{1/2} t^{1/2} |K\{t(1 - t)\}|^{\delta - 3/2} dt \\ & \leq K \int_{0}^{1} t^{\delta - 1} (\frac{1}{2})^{\delta - 3/2} dt = \frac{K}{\delta} 2^{3/2 - 2\delta} \end{aligned}$$

using (6.9) and assumption (b).

Similarly, using (6.10) we get

$$\int_{1/2}^{1} |R_n(t, t)|^{1/2} |\varphi'(t)| dt \leq \frac{K}{\delta} 2^{3/2-2\delta}.$$

Combining the two, we have (6.4). The proof of (6.5) is similar.

We are now in a position to prove the following theorem.

Theorem 6.2. Let $X_n(t)$, $Y_n(t)$, X_n and Y_n be as defined earlier. Let the following conditions be satisfied:

(a) $\lim_{m,n\to+\infty} E(X_m(t) X_n(t)) = \lim_{m,n\to+\infty} E(Y_m(t) Y_n(t)) = \lim_{m\to+\infty} \frac{1}{m} = \lim_{m\to+\infty} E(X_m(t) X_n(t)) = \lim_{m\to+\infty} \frac{1}{m} = \lim_{m\to+\infty} E(X_m(t) X_n(t)) = \lim_{m\to+\infty} E$

(b)
$$\max_{1 \le i \le n} \frac{|C_{ni}|}{s_n} = O(\frac{1}{\sqrt{n}}).$$

(c) $|\varphi'(t)| \le K \{t(1-t)\}^{\delta-3/2}$ for some $\delta > 0$ and a generic constant K.

Then, given $\epsilon > 0$, there exist Gaussian random variables X and Y and a positive integer n_0 such that, $n \ge n_0$ entails

and

Remark. Condition (a) can be replaced by $\lim_{n\to +\infty} K_n(s, t) = K(s, t)$ where $K_n(s, t) = E(X_n(s) X_n(t))$ and condition of corollary 4.2 for $Y_n(t)$. Then it follows from Shorack (1973) and our corollary 4.2 respectively that $X_n(t)$ and $Y_n(t)$ converge in L_2 to Gaussian processes X(t) and Y(t). We examine these conditions more closely in section 8.

<u>Proof of Theorem 6.2.</u> Consider $Y_n(t)$. By theorem 4.1 (or corollary 4.2) and theorem 5.1, $Y_n(t) \xrightarrow{L_2} Y(t)$ where Y(t) is Gaussian with kernel

(6.14)
$$R(s, t) = \lim_{\substack{n \to +\infty}} R_n(s, t)$$

= $\lim_{\substack{n \to +\infty}} \frac{1}{s_n^2} \sum_{i=1}^n C_{ni}^2 \{F_{ni}(F_n^{-1}(s))(1 - F_{ni}(F_n^{-1}(t)))\}, s \le t.$

Let

(6.15)
$$Y = \int_{0}^{1} Y(t) \varphi'(t) dt.$$

$$Var Y = \int_{0}^{1} \int_{0}^{1} \varphi'(s) \varphi'(t) R(s, t) ds dt$$

$$\leq \{ \int_{0}^{1} |\varphi'(t)| \{R(t, t)\}^{1/2} dt \}^{2}$$

$$= \{ \int_{0}^{1} \lim_{n \to +\infty} |\varphi'(t)| \{R_{n}(t, t)\}^{1/2} dt \}^{2}$$

$$\leq \{ \lim \inf_{n \to +\infty} \int_0^1 \left| \phi'(t) \right| \left\{ R_n(t,\ t) \right\}^{1/2} dt \}^2 < + \infty \ .$$

Observe that by theorem 6.1, $\operatorname{Var} Y_n$ is finite uniformly in n.

Thus

$$\begin{split} \|Y_{n} - Y\| &= \|\int_{0}^{1} (Y_{n}(t) - Y(t)) \phi'(t) dt \| \\ &\leq \int_{0}^{1} \|Y_{n}(t) - Y(t)\| |\phi'(t)| dt \longrightarrow 0 \text{ as } n \to +\infty \end{split}$$

because $\|Y_n(t) - Y(t)\| |\phi'(t)| \longrightarrow 0$ and is dominated by the integrable sequence,

$$(\|Y_n(t)\| + \|Y(t)\|) |\varphi'(t)|.$$

Thus,

$$\|Y_n - Y\| < \varepsilon$$
 for n sufficiently large.

The proof of $\|X_n - X\| < \varepsilon$ is similar. X can be taken to be,

$$X = \frac{1}{\int_{n s_n}} \int_{0}^{1} X(t) \varphi'(t) dC(t)$$

where X(t) is Gaussian with $K(s, t) = \lim_{n \to +\infty} K_n(s, t)$ and

$$C(t) = \sum_{i=1}^{n} C_{ni} F_{ni}(F_{n}^{-1}(t)).$$

7. Asymptotic Normality of Simple Linear Rank Statistics.

We are now in a position to prove the asymptotic normality of the statistic, S_n , defined in (2.1), namely

$$S_n = \sum_{i=1}^{n} C_{ni} \varphi(\frac{R_{ni}}{n+1}) .$$

We make the following assumptions:

(a)
$$|\phi^{(i)}(t)| \le K\{t(1-t)\}^{\delta-i-1/2}$$
, $i = 0, 1; K, \delta$ being generic constants.

(b) $X_n(t)$ and $Y_n(t)$ satisfy condition of theorem 4.2 (or corollary 4.3).

(c)
$$\max_{1 \leq i \leq n} \frac{|C_{ni}|}{(\text{Var } S_n)^{1/2}} = O(\frac{1}{\sqrt{n}}).$$

We then have the following theorem:

Theorem 7.1. Let the independent random variables X_{nl}, ..., X_{nn} with continuous distribution functions F_{nl}, ..., F_{nn} be such that conditions

(a), (b), and (c) above are satisfied. Then there exists a Gaussian random variable S with mean O and variance 1 such that

(7.1)
$$\frac{S_n - \mu_n}{(\text{Var } S_n)^{1/2}} \longrightarrow S \text{ in probability, Var } S_n \neq 0,$$

where

(7.2)
$$\mu_{n} = \int_{0}^{1} \varphi(t) d C(t),$$

$$C(t) = \sum_{i=1}^{n} C_{ni} F_{ni}(F_{n}^{-1}(t)).$$

Further, variance of Sn can be replaced by the approximate variance,

(7.3)
$$s_n^2 = \sum_{i=1}^n \text{Var } A_{ni}(X_{ni}) = \sum_{i=1}^n s_{ni}^2$$

where

(7.4)
$$A_{ni}(x) = \frac{1}{n} \sum_{j=1}^{n} (C_{nj} - C_{ni}) \int_{-\infty}^{\infty} \{I(x \le y) - F_{ni}(y)\} \phi'(F_{n}(y)) dF_{nj}(y).$$

 $\underline{\text{Proof.}}$ We can express the statistic S_n as

(7.5)
$$S_n = \int_0^1 \varphi(\frac{n}{n+1} H_n(t)) dC_n(t)$$

where

(7.6)
$$c_n(t) = \sum_{i=1}^{n} c_{ni} I(X_{ni} \le F_n^{-1}(t))$$

(7.7)
$$H_n(t) = \frac{1}{N} \sum_{i=1}^{n} I(X_{ni} \leq F_n^{-1}(t)).$$

It is easily verified that by linear approximation, S_n is expressible

(7.8)
$$S_n = \mu_n + B_{1N} + B_{2N} + D_{1N} + D_{2N} + D_{3N}$$

where μ_n is as in (7.2),

as

(7.9)
$$B_{ln} = \int_0^1 \varphi(t) d(C_n(t) - C(t))$$

(7.10)
$$B_{2n} = \int_0^1 (H_n(t) - t) \varphi'(t) dC(t)$$

(7.11)
$$D_{ln} = \frac{-1}{n+1} \int_{0}^{1} H_{n}(t) \varphi'(t) dC(t)$$

(7.12)
$$D_{2n} = \int_0^1 (H_n(t) - t) \varphi'(t) d(C_n(t) - C(t))$$

(7.13)
$$D_{3n} = \int_{0}^{1} \{ \varphi(\frac{n}{n+1} H_{n}(t)) - \varphi(t) - (\frac{n}{n+1} H_{n}(t) - t) \varphi'(t) \} dC_{n}(t).$$

We will show that,

(i)
$$|\mu_n| < + \infty$$
,

(ii)
$$\frac{1}{s_n}$$
 (B_{ln} + B_{2n}) converges in probability to a normal random variable.

(iii)
$$D_{in} = o_p(s_n)$$
, $i = 1, 2, 3$.

The following inequalities are immediate.

(7.14)
$$|C_n(t)| \le n \max_{1 \le i \le n} |C_{ni}| H_n(t)$$

(7.15)
$$|C(t)| \leq n \max_{1 \leq i \leq n} |C_{ni}| F_n(t).$$

Thus
$$|\mu_n| \leq |n \max_{1 \leq i \leq n} |C_{ni}| \frac{1}{n} \int_0^1 \varphi(t) \sum_{i=1}^n dF_{ni}(F_n^{-1}(t))$$

$$\leq n \max_{1 \leq i \leq n} |C_{ni}| \int_0^1 |\varphi(t)| dt < + \infty \text{ by assumption (a). This proves (i)}$$

Proof of (ii): Consider $B_{ln} = \int_{0}^{l} \varphi(t) d(C_{n}(t) - C(t))$.

Integration by parts yields,

(7.16)
$$B_{ln} = \{C_n(t) - C(t)\}\phi(t) \Big|_{0}^{1} - \int_{0}^{1} \phi'(t) \{C_n(t) - C(t)\}dt.$$

Claim: $\frac{1}{s_n} (C_n(t) - C(t)) \varphi(t) \longrightarrow 0$ in probability as $t \longrightarrow 0$ or 1.

Because an argument similar to that in the proof of Theorem 6.1 yields

$$(7.17) \quad \text{Var } \{\frac{\phi(t)(C_n(t) - C(t))}{s_n}\} \leq O(1) \text{ min } [t \phi^2(t), (1-t) \phi^2(t)]$$

$$\leq K^2 \text{ min } [t^{\delta}(1-t)^{\delta-1}, t^{1-\delta}(1-t)^{\delta}],$$

$$+ O < t < 1 \text{ which proves the claim.}$$

Next, observe that $\frac{1}{s_n}$ (C_n(t) - C(t)) = Y_n(t) and $\sqrt{n}(H_n(t) - t) = X_n(t)$. Hence,

$$\frac{B_{ln}}{s_n} = -Y_n \quad \text{and} \quad$$

$$\frac{B_{2n}}{s_n} = X_n$$

where X and Y have been defined in the preceding section.

By theorem 6.1, for each $\varepsilon > 0$, there exist X and Y Gaussian such that,

$$\|X_n - X\| < \varepsilon/2$$
 and $\|Y_n - Y\| < \varepsilon/2$.

Thus, $\|(X_n - Y_n) - (X - Y)\| < \epsilon$.

It remains to show that X - Y is Gaussian. We can write

$$Z_n(t) = X_n(t) - Y_n(t)$$
.

By rearranging terms of $X_n(t)$ and $Y_n(t)$, $Z_n(t)$ can be written as

$$\sum_{i=1}^{n} (\frac{1}{\sqrt{n}} - \frac{c_{ni}}{s_{n}}) \{I(X_{ni} \leq F_{n}^{-1}(t)) - F_{ni}(F_{n}^{-1}(t))\}$$

and conditions of the bounded Liapunov theorem are satisfied. Thus $Z_n(t)$ is asymptotically Gaussian.

Further, $X_n - Y_n$ is a linear mapping on $Z_n(t)$ and since X - Y is the limit of $X_n - Y_n$, must be Gaussian. This establishes the asymptotic normality of $X_n - Y_n$.

We shall examine the behavior of X - Y more closely in section 8. This proves (ii).

Here we have taken $s_n = Var(X_n - Y_n)$. Later we find an approximation for s_n .

<u>Proof of (iii)</u>: We shall simplify the notation by writing $x = F_n^{-1}(t)$ and

$$H_{n}(x) = \frac{1}{n} \sum_{i=1}^{n} I(X_{ni} \le x)$$

$$C_{n}(x) = \frac{1}{n} \sum_{i=1}^{n} C_{ni} I(X_{ni} \le x)$$

$$F_{n}(x) = \frac{1}{n} \sum_{i=1}^{n} F_{ni}(x)$$

$$C(x) = \sum_{i=1}^{n} C_{ni} F_{ni}(x)$$

$$\frac{D_{1n}}{S_{n}} = \frac{-1}{(n+1)S_{n}} \int_{-\infty}^{\infty} H_{n}(x) \varphi'(F_{n}(x)) dC_{n}(x).$$

Hence

(7.18)
$$\left|\frac{D_{1n}}{S_n}\right| \leq \frac{1}{nS_n} \left|\sum_{i=1}^n \phi'(F_n(X_{ni}))C_{ni}\right| \leq \frac{1}{n} \sum_{i=1}^n |V_{ni}|$$

(as $C_n(x)$ assigns measure C_{ni} when $x = X_{ni}$ and since $H_n(x) \le 1$). Where,

(7.19)
$$V_{ni} = \frac{C_{ni}}{s_n} \varphi'(F_n(X_{ni})).$$

Then, it suffices to show that

$$\frac{1}{n}\sum_{i=1}^{n}|V_{ni}| \longrightarrow 0 \text{ in probability as } n \longrightarrow +\infty.$$

This follows from "Particular case 10," Loéve (1963), p. 241, if we show

that
$$\sum_{i=1}^{n} \frac{E |V_{ni}|^{\alpha}}{\alpha} < +\infty$$
, uniformly in n for some $0 < \alpha < 1$. Take

 $\alpha = 2/3$; then

$$\sum_{i=1}^{n} \frac{\mathbb{E}|V_{ni}|^{2/3}}{n^{2/3}} = \frac{1}{n^{2/3}} \sum_{i=1}^{n} \frac{|C_{ni}|^{2/3}}{s_{n}^{2/3}} \mathbb{E}\{F_{n}(X_{ni})(1 - F_{n}(X_{ni}))\}^{2/3(\delta - 3/2)}$$

$$\leq \max_{1 \leq i \leq n} \frac{|c_{ni}|^{2/3}}{s_n^{2/3}} \cdot \frac{1}{n^{2/3}} \sum_{i=1}^{n} \int_{-\infty}^{\infty} \{F_n(x)(1 - F_n(x))\}^{2\delta/3 - 1} dF_{ni}(x)$$

=
$$O(1) \frac{1}{n} \sum_{i=1}^{n} \int_{-\infty}^{\infty} \{F_n(x) (1 - F_n(x))\}^{2\delta/3-1} dF_{ni}(x)$$

=
$$O(1) \int_{-\infty}^{\infty} \{F_n(x)(1 - F_n(x))\}^{2\delta/3-1} dF_n(x) < +\infty$$
 uniformly in n.

We have used the fact

$$\max_{1 \le i \le n} \left| \frac{c_{ni}}{s_n} \right|^{2/3} = O(\frac{1}{n^{1/3}}).$$

Thus $D_{ln} = o_{p}(s_{n})$.

Next consider,

$$D_{2n} = \int_{-\infty}^{\infty} (H_n(x) - F_n(x)) \varphi'(F_n(x)) d(C_n(x) - C(x)).$$

Note that, given $\varepsilon>0$, $0<\delta'<1/2$, there exists a constant $C(\varepsilon,\,\delta')$ such that,

(7.19)
$$P(\sup_{x} \frac{|H_{n}(x) - F_{n}(x)|}{\{F_{n}(x)(1-F_{n}(x))\}^{\delta'-1/2}} > \frac{C(\varepsilon, \delta')}{\sqrt{n}}) < \varepsilon.$$

Thus on a set of probability > 1 - ϵ ,

$$\left| H_n(x) - F_n(x) \right| \left| \phi'(F_n(x)) \right| \leq \frac{K \cdot C(\varepsilon, \delta')}{\sqrt{n}} \left\{ F_n(x) (1 - F_n(x)) \right\}^{\delta * - 1}$$

where $\delta * = \delta - \delta'$ and $\delta' < \delta$ is chosen.

Thus it suffices to show that,

$$(7.20) \qquad \frac{K C(\varepsilon, \delta')}{\sqrt{n s_n}} \int_{-\infty}^{\infty} \{F_n(x)(1 - F_n(x))\}^{\delta *-1} d(C_n(x) - C(x)) \longrightarrow 0$$

in probability.

We use the Liapunov criterion for degenerate convergence, (p. 275, B(i), Loéve (1963)),

$$\begin{split} \frac{K}{s \sqrt[K]{n}} & \int_{-\infty}^{\infty} \{F_n(x)(1 - F_n(x))\}^{\delta^{*-1}} d C_n(x) \\ &= \frac{K}{\sqrt{n}} \sum_{i=1}^{n} C_{ni} \{F_n(X_{ni})(1 - F_n(X_{ni}))\}^{\delta^{*-1}}. \end{split}$$

Let

(7.21)
$$V_{ni} = \frac{\sqrt{n} c_{ni}}{s_n} \{F_n(X_{ni})(1 - F_n(X_{ni}))\}^{\delta^*-1}.$$

Then,

$$(7.22) \qquad \frac{1}{\sqrt{n}} \sum_{i=1}^{n} C_{ni} \{F_{n}(X_{ni})(1 - F_{n}(X_{ni}))\}^{\delta^{*-1}}$$

$$= \frac{1}{n} \sum_{i=1}^{n} V_{ni}.$$

It remains to show $\frac{1}{n}\sum_{i=1}^{n}(V_{ni}-EV_{ni})\longrightarrow 0$ in probability. This will be done if we show that for some $\alpha>0$,

$$(7.23) \qquad \frac{1}{n^{1+\alpha}} \sum_{i=1}^{n} E|V_{ni}|^{\alpha+1} \longrightarrow 0.$$

We choose an $\alpha > 0$ such that, $(1 + \alpha)(\delta^* - 1) > -1$. (I.e., $0 < \alpha < \frac{\delta^*}{1 - \delta^*}$). Then $\frac{1}{n^{1+\alpha}} \sum_{i=1}^{n} E|V_{ni}|^{1+\alpha}$

$$\leq \frac{1}{n^{\alpha}} \cdot \frac{1}{n} \left| \frac{\sqrt{n \max |C_{ni}|}}{s_n} \right|^{1+\alpha} \cdot \sum_{i=1}^{n} E\{F_n(X_{ni})(1 - F(X_{ni}))\}^{(1+\alpha)(\delta *-1)}$$

$$= O(\frac{1}{n^{\alpha}}) \cdot \frac{1}{n} \cdot \sum_{i=1}^{n} \int_{-\infty}^{\infty} \{F_n(x)(1 - F_n(x))\}^{(1+\alpha)(\delta *-1)} dF_{ni}(x)$$

$$= O(\frac{1}{n^{\alpha}}) \cdot \int_{-\infty}^{\infty} \{F_n(x)(1 - F_n(x))\}^{(1+\alpha)(\delta *-1)} dF_n(x) \longrightarrow 0 \text{ as } n \longrightarrow +\infty$$

because the integral is bounded uniformly for all n. This proves (7.23).

Again we have used the fact

$$\sqrt{n} \max_{1 \le i \le n} |C_{ni}|/s_n = O(1).$$

This establishes $D_{2n} = o_p(s_n)$. Consider,

$$D_{3n} = \int_{-\infty}^{\infty} \{ \varphi(\frac{n}{n+1} H_n(x)) - \varphi(F_n(x)) - (\frac{n}{n+1} H_n(x) - F_n(x)) \varphi'(F_n(x)) \} dC_n(x).$$

We note the following: with

(7.24)
$$c_{3n} = \frac{D_{3n}}{\sqrt{n} s_n}$$

it suffices to prove

(7.25)
$$C_{3n} = o_{p}(1/\sqrt{n}).$$

Observe that

(7.26)
$$|C_{3n}| \le O(1) \int_{-\infty}^{\infty} |\varphi(\frac{n}{n+1} H_n(x)) - \varphi(F_n(x)) - (\frac{n}{n+1} H_n(x)) - F_n(x)| \varphi'(F_n(x)) dH_n(x)$$

because of the fact

$$\max_{1 \le i \le n} \left| \frac{C_{ni}}{s_n \sqrt{n}} \right| = O(\frac{1}{n}).$$

The proof that the right hand side of (7.26) is $o_p(\frac{1}{\sqrt{n}})$ can be found in Puri and Sen (1971), pp. 401-405. This proves theorem 7.1.

<u>Variance Computation</u>: Since by (ii) $D_{in} = o_p(s_n)$, i = 1, 2, 3, we can take s_n to be the variance of $B_{1n} + B_{2n}$.

In order to simplify our notation, we write $y = F_n^{-1}(t)$. Observe that,

$$C(t) = \sum_{j=1}^{n} C_{nj} F_{nj} (F_{n}^{-1}(t)) = \sum_{j=1}^{n} C_{nj} F_{nj}(y) = C(y), \text{ say.}$$

With these transformations, we can write

$$(7.27) \quad B_{ln} + B_{2n} = \frac{1}{n} \int_{-\infty i=1}^{\infty} \{I(X_{ni} \leq y) - F_{ni}(y)\} \phi'(F_{n}(y)) dC(y)$$

$$- \int_{-\infty i=1}^{\infty} C_{ni} \{I(X_{ni} \leq j) - F_{nk}(y)\} \phi'(F_{n}(y)) dF_{n}(y)$$

$$= \sum_{i=1}^{n} A_{ni}(X_{ni})$$

where

$$\begin{split} A_{ni}(x) &= \frac{1}{n} \int_{-\infty}^{\infty} \{ I(x \le y) - F_{ni}(y) \} \ \phi'(F_{n}(y)) \ dC(y) \\ &- C_{ni} \int_{-\infty}^{\infty} \{ I(x \le y) - F_{ni}(y) \} \ \phi'(F_{n}(y)) \ dF_{n}(y) \\ &= \frac{1}{n} \sum_{j=1}^{n} C_{nj} \int_{-\infty}^{\infty} \{ I(x \le y) - F_{ni}(y) \} \ \phi'(F_{n}(y)) \ dF_{nj}(y) \\ &- \frac{1}{n} \sum_{j=1}^{n} C_{ni} \int_{-\infty}^{\infty} \{ I(x \le y) - F_{ni}(y) \} \ \phi'(F_{n}(y)) \ dF_{nj}(y). \end{split}$$

Thus,

(7.28)
$$A_{ni}(x) = \frac{1}{n} \sum_{j=1}^{n} (C_{nj} - C_{ni}) \int_{-\infty}^{\infty} \{I(x \le y) - F_{ni}(y)\} \phi'(F_{n}(y)) dF_{nj}(y).$$

Thus, we can express $B_{ln} + B_{2n}$ as the sum of independent random variables, $A_{ni}(X_{ni})$. If we write,

$$s_{ni}^2 = Var A_{ni}(X_{ni}),$$

we can then take

$$s_n^2 = \sum_{i=1}^n s_{ni}^2$$
.

8. Asymptotic Degeneracy of Sn:

From the expression (7.8) for S_n , namely,

$$S_n = \mu_n + B_{1n} + B_{2n} + D_{1n} + D_{2n} + D_{3n}$$

it is clear that we need only examine the limiting behavior of the terms $B_{ln} + B_{2n}$. With the help of the expression (7.4) for $A_{ni}(\cdot)$ we can express $B_{ln} + B_{2n}$ as a sum of independent random variables which would enable standard tools from stability theory to be used. But a glance at the expression for $A_{ni}(\cdot)$ suffices to convince us of the impracticality of the situation. We shall adopt a different procedure using the variance inequalities proved in section 6.

Clearly, s_n are only normalizing constants and we can replace C_{ni}/s_n by C_{ni} themselves but now with the condition,

(8.1)
$$\max_{1 < i < n} |C_{ni}| = O(\frac{1}{\sqrt{n}}).$$

Then,

(8.2)
$$X_n = \frac{1}{\sqrt{n}} \int_0^1 X_n(t) \varphi'(t) dC(t)$$

(8.3)
$$Y_n = \int_0^1 Y_n(t) \varphi'(t) dt$$

where now

(8.4)
$$Y_n(t) = \sum_{i=1}^n C_{ni} \{I(X_{ni} \le F_n^{-1}(t)) - F_{ni}(F_n^{-1}(t))\}.$$

In view of (8.1), $Y_n(t)$ is asymptotically either Gaussian or degenerate. We next examine conditions for the degeneracy (or non-degeneracy) of $X_n - Y_n$ in the limit.

Assuming that the distribution functions F_{ni} possess densities $F_{ni}' = f_{ni}$, we can express

(8.5)
$$X_n = \int_0^1 \varphi'(t) \frac{C'(t)}{\sqrt{n}} X_n(t) dt$$

where

(8.6)
$$C'(t) = \{\frac{1}{n} \sum_{i=1}^{n} f_{ni}(F_{n}^{-1}(t))\}^{-1} \{\sum_{i=1}^{n} C_{ni} f_{ni} (F_{n}^{-1}(t))\}.$$

We then have the following proposition.

Proposition. Let condition (8.1) be satisfied. With X_n and Y_n defined by (8.2) and (8.3) respectively, $S_n = X_n - Y_n$ is asymptotically degenerate whenever

(8.7)
$$\lim_{n \to +\infty} \sum_{i=1}^{n} \left(\frac{C'(t)}{n} - C_{ni} \right)^{2} F_{ni}(F_{n}^{-1}(t)) (1 - F_{ni}(F_{n}^{-1}(t))) = 0$$

almost everywhere on (0, 1).

It is, of course, assumed that ϕ and ϕ' satisfy the same conditions as before.

Proof. It is easy to verify that

$$S_{n} = X_{n} - Y_{n} = \int_{0}^{1} \phi'(t) \sum_{i=1}^{n} \left(\frac{C'(t)}{n} - C_{ni} \right) \left\{ I(X_{ni} \leq F_{n}^{-1}(t)) - F_{ni}(F_{n}^{-1}(t)) \right\} dt.$$

Hence

$$\begin{aligned} \text{Var S}_{n} &= \int_{0}^{1} \int_{0}^{1} \phi'(s) \phi'(t) \sum_{i=1}^{n} \left| \frac{C'(t)}{n} - C_{ni} \right|^{2} \left[F_{ni}(F_{n}^{-1}(s) \wedge F_{n}^{-1}(t)) - F_{ni}(F_{n}^{-1}(s)) \right] ds dt \\ &= F_{ni}(F_{n}^{-1}(s)) F_{ni}(F_{n}^{-1}(t)) ds dt \\ &\leq \left[\int_{0}^{1} \left| \phi'(t) \right| \left[\sum_{i=1}^{n} \left| \frac{C'(t)}{n} - C_{ni} \right|^{2} F_{ni}(F_{n}^{-1}(t)) (1 - F_{ni}(F_{n}^{-1}(t))) \right]^{1/2} dt \right]^{2}. \end{aligned}$$

By theorem 6.1, (variance inequalities) the last quantity above is uniformly bounded in N. Now it is easily verified that (8.7) entails $\operatorname{Var} S_n \longrightarrow 0$. This completes the proof.

Remark: A consequence of condition (8.7) is that whether S_n is asymptotically degenerate or not depends very heavily on the underlying distributions and it may not be possible to secure nondegeneracy by any choice of the regression constants C_{ni} and the score generating function φ . The difficulty is that the so-called Kolmogorov-Smirnov bounds, namely

$$P(\sup_{t} \frac{1}{\sqrt{n}} | \sum_{i=1}^{n} \{I(X_{ni} \leq F_n^{-1}(t)) - F_{ni}(F_n^{-1}(t))\}| > \alpha)$$

can be very small, when the underlying distributions are nonidentical. An example following theorem 2.11.8, p. 41 of Puri-Sen (1971), illustrates this point.

Acknowledgements: Results of this paper are based on a part of the author's doctoral dissertation written at Indiana University. The author is extremely grateful to Professor Madan L. Puri who suggested this problem and provided inspiring guidance. He also thanks Professor Victor Goodman for his help.
